

## Master 2: *International Centre for Fundamental Physics*

### INTERNSHIP PROPOSAL

Laboratory name: Laboratoire Ondes et Matière d'Aquitaine (LOMA)

CNRS identification code: 5798

Internship directors' surnames: Thomas Salez, Yacine Amarouchene

E-mails: thomas.salez@cnrs.fr, yacine.amarouchene@u-bordeaux.fr

Phone numbers: +33(0)540002501, +33(0)540003036

Web pages:

[www.loma.cnrs.fr/thomas-salez](http://www.loma.cnrs.fr/thomas-salez), [www.researchgate.net/profile/Yacine-Amarouchene](http://www.researchgate.net/profile/Yacine-Amarouchene)

Internship location: University of Bordeaux, LOMA, 351 cours de la Libération, 33405 Talence, France

Thesis possibility after internship: YES

Funding: No

If YES, which type of funding:

#### **Brownian motion in complex environnements**

*Motility of microscopic biological entities with the aim of reaching specific targets is a central question of biophysics, as evidenced by: cancer metastasis, durotaxis of stem cells, antibody recognition, or DNA replication, among numerous other examples. In an idealization attempt, this problem could perhaps be reduced to simple mechanics through a minimal combination of essential ingredients: viscous flow, elastic boundaries, confined environment, charges and thermal fluctuations. In echo to this point, a key problem of modern nanoscience amounts to understanding how to build the missing links between the antinomic molecular and continuum descriptions of matter or, stated differently, between the bottom-up and top-bottom approaches of condensed matter. Therefore, once again, combining continuum ingredients such as hydrodynamics and elasticity, together with molecular fluctuations at small scales, emerges as a crucial task. Right from the above arguments, the study of Brownian motion in crowded and soft-lubricated environments appears as one of the canonical problems of biophysics and nanophysics. Despite the obvious character of this statement, it is intriguing to notice that theoretical studies are scarce on the topic, and that experimental pieces of evidence are inexistant - to the best of our knowledge. The "EMetBrown" project thus naturally aims at filling this gap, and further utilizing the associated knowledge production towards applications as various and important as particle trapping and transport, surface patterning, non-contact rheology, or biological filtering. Our strategy is to develop several simultaneous experiments, within an existing national consortium, and together with an international network of collaborators that are experts in the field of elastohydrodynamics. The various techniques involve: Mie holography, optical tweezers, atomic-force microscopy, microfluidics... Besides, numerical and theoretical efforts will be dedicated to the resolution of the non-trivial governing system of equations: a 3D non-linear coupled Langevin problem including multiplicative noise and external potential. The student, interested by some of these aspects of our activities should not hesitate to contact us for more details.*
